

ABSTRACT

The present invention relates to a method of treatment of Parkinson's
5 disease, and to the use of antisense oligonucleotides or triplex oligonucleotides
introduced into targeted brain structures to decrease the function of brain circuits
known to be overactive in the Parkinsonian brain. Antisense or triplex
oligonucleotides are targeted to the internal globus pallidus and/or substantia nigra
pars reticulata (SNr) where the expression of glutamic acid decarboxylase (GAD₆₇,
10 GAD₆₅, or a combination of the two isoforms) is downregulated. The present
invention also relates to a method of treatment of Parkinson's disease where
antisense or triplex oligonucleotides are targeted to the internal globus pallidus
and/or substantia nigra pars reticulata for the downregulation of glutamate
receptors. The present invention further relates to a method of treatment of
15 Parkinson's disease where antisense or triplex oligonucleotides are targeted to the
thalamic motor nuclei for the downregulation of GABA receptors.
